1. My Responsibility

As **CIO / Repository Lead**, I created and maintained the technical workspace for the K.I.V.A.S. project. I was responsible for the GitHub repository, its folder architecture, file placement, commits, and publication of repository changes.

My goal was to keep the project **structured, traceable, and ready for review**. GitHub was therefore used not only as file storage, but as the team's **version-controlled source of truth**.

2. Repository Architecture

I designed the repository around **separation of concerns**: course content, study guides, slides, assets, references, planning, and evidence are stored in dedicated locations instead of being mixed in one directory.

```
KIVAS/
├── README.md
├── CONTRIBUTING.md
├── content/
├── study-guide/
├── slides/
├── assets/        [images / diagrams]
├── videos/        [scripts / storyboards]
├── references/
├── project-plan/
└── evidence/
```

This structure improves **maintainability** and makes the repository easier to navigate as the project grows.

3. Version Control and Repository Management

I used **GitHub** and **Git Bash** for day-to-day repository operations. My work included:

- creating the GitHub repository and initial folder hierarchy;
- creating and moving files when the project structure changed;
- checking file locations and naming consistency before publishing;
- committing changes so the repository kept a visible change history;
- publishing repository updates to GitHub.

Before a change was published, I checked whether the file belonged in the correct directory and whether an older or duplicate version could create confusion. This provided a simple form of **change control** and helped preserve **content integrity**.

4. How I Used AI

I used ChatGPT as a **supporting technical tool**, not as an autonomous repository manager. AI was mainly useful when I forgot the syntax or sequence of a Git/Git Bash command, and when I needed help improving wording or formatting inside Markdown (**.md**) files.

The final decisions about repository architecture, file placement, and whether a change should be committed or published remained my responsibility.

5. Repository Workflow

1	2	3	4	5
Create / update	Check file	Place correctly	Commit	Publish

Our project did **not** use feature branches, pull requests, CI/CD, or an advanced merge workflow. Updates were managed directly through the main working repository. This report intentionally does not claim practices that were not part of our actual process.

6. My Decisions and Contribution

My main contribution was establishing the technical foundation through which project materials could remain organized and reviewable. I personally:

- created the repository and designed its folder architecture;
- maintained file organization as new materials were added;
- used Git Bash for repository and file operations;
- committed and published repository changes;
- reviewed files before publishing;
- used AI only when command recall or Markdown editing was needed.

A key design decision was to separate **content, presentation, assets, references, planning, and evidence**. This supports **maintainability, traceability, and scalability** without adding unnecessary complexity.

7. Quality Control

Before publishing changes, I checked:

Correct location	The file is stored in the folder that matches its purpose.
Naming consistency	File and folder names remain understandable and predictable.
Duplicate risk	Older or duplicate versions do not create ambiguity.
Readable Markdown	Markdown content remains clear and properly structured.
Repository history	The published change is represented by a commit and can be traced later.

8. Technical Value of My Role

The CIO / Repository Lead role connected different deliverables into one controlled project environment. The value of this work can be summarized through four principles:

Traceability	Repository history makes changes reviewable.
Maintainability	Files can be updated without reorganizing the whole project.
Consistency	Project materials follow one clear structure.
Scalability	New content can be added without repository disorder.

For this reason, my contribution was not limited to uploading files. My responsibility was to maintain the **technical structure through which the team's work was organized and published**.

9. Evidence and Transparency Note

Evidence of my contribution can be found directly in the project GitHub repository, including repository creation, folder structure, commit history, moved or added files, Markdown documents, and published changes.

AI assistance was limited to occasional Git/Git Bash command recall and Markdown text preparation. AI did not independently manage the repository, decide its architecture, or publish team work without my involvement.

Prepared for instructor review
